

Appendix 2.2. Regulations for Practical Industry Initiatives, Three-Stage Agora Pipeline, and Algorithmic Technical Supervision

Section 1. General Provisions and Core Architecture

1.1. Executive Scope and Purpose

These Regulations establish the normative operational rules, procedural pipeline, and algorithmic supervision frameworks governing Practical Industry Initiatives within the Agora ecosystem. The goal of this framework is to ensure a deterministic, auditable, and automated progression of industrial proposals from public incubation to direct execution while maintaining system invariants and cryptographic integrity.

1.2. Architectural Role of Agora-Tribune

The Agora-Tribune platform serves as the decentralized entry point and public incubator for economic, industrial, and technological initiatives. It provides a structured environment for submitting proposal manifestos, conducting open multi-stakeholder evaluations, performing parameter stress-testing, and finalizing execution topology.

1.3. Fundamental Architectural Invariants

All practical initiatives deployed through the Agora platform must conform strictly to the following invariants:

- Algorithmic Determinism: Financial capital flows and operational execution states are controlled exclusively by automated smart contracts without manual discretionary intervention.

- Cryptographic Verification: No initiative parameters or financial allocations can be finalized without prior validation via Zero-Knowledge (ZK) oracles and Trusted Execution Environment (TEE) nodes.
- Institutional Non-Intermediation: The engine functions independently of direct corporate Special Purpose Vehicles (SPVs) or centralized banking asset custody.

Section 2. The Three-Stage Agora Pipeline

2.1. Overview of Pipeline Stages

To maintain ecosystem reliability and prevent economic instability, every initiative must sequentially complete the Three-Stage Agora Pipeline prior to capital deployment.

2.2. Stage 1: Tribune Phase (Initiation and Public Discussion)

- Proposal Submission: Initiative authors submit a comprehensive digital manifesto detailing industrial parameters, capital requirements, operational roadmaps, and economic metrics.
- Public Evaluation & Consultation: Ecosystem participants, domain specialists, and node operators conduct transparent reviews, feasibility analyses, and open Q&A sessions.
- Consensus & Preliminary Validation: Proposals gather community validation metrics and undergo initial syntax, logic, and structural parameter checks.

2.3. Stage 2: Algorithmic Technical Supervision & Verification

- Algorithmic Stress-Testing: Automated simulation models evaluate the initiative's economic sustainability, risk profile, and liquidity requirements under varying market scenarios.
- ZK-Oracle Asset Verification: Zero-knowledge proofs verify physical supply chain connections, resource availability, and external audit claims without leaking sensitive business data.
- TEE Hardware Computation: Computational models for performance tracking and milestone triggers are verified within hardware-isolated TEE enclaves to ensure execution integrity.

2.4. Stage 3: Approval and Deployment Topology

- Formal Protocol Approval: Upon passing Stage 2 algorithmic verification, the proposal transitions to formal system approval status.

- Smart Contract Compilation: Initiative parameters are automatically compiled into standard, executable escrow pool smart contract topologies.
- Execution Coupling: The compiled smart contract framework bridges directly into the financial clearing layer for automated operations.

Section 3. Financial Mechanics and Invariant Fiscal Splits

3.1. Overview of Fiscal System Standard

The financial architecture operates on strict, programmatic splits designed to sustain network operations, fund node infrastructure, support continuous core software updates, and ensure legal copyright royalty payments.

3.2. Inbound Fiscal Allocation Split

All gross inbound financial inflows directed toward an approved practical initiative are subject to an inbound fiscal split of exactly 2.50%. The remaining 97.50% of inbound capital is credited directly to the project's T_net equity capital balance.

- Inbound Split Distribution Breakdown:
    - Equity Capital Balance (T_net): 97.50% credited directly to project execution and operational deployment.
    - Regeneration Reserve Fund ($S_{reserve}$): 0.80% allocated to ecosystem risk mitigation and liquidity stabilization reserves.
    - TEE Nodes and ZK-Oracles Infrastructure Fund: 0.80% allocated to incentivize and maintain hardware verification nodes and oracle networks.
    - Lightweight Core Modernization Fund: 0.40% dedicated to ongoing development and maintenance of the core engine microkernel.
    - IP Royalty (Copyright): 0.50% allocated continuously to intellectual property rightsholders.

3.3. P2P Barter Transaction Mechanics

Direct peer-to-peer (P2P) barter swaps, industrial asset exchanges, and resource balancing transactions within the system carry a standardized transaction fee of 1.50%.

- P2P Barter Split Distribution:
    - Infrastructure and Regeneration Reserve ($S_{reserve}$ / TEE / ZK): 1.00% allocated to joint infrastructure support and system reserve maintenance.

    - IP Royalty (Copyright): 0.50% allocated to intellectual property rights compensation.

3.4. Transit Royalty Mechanics

For cross-boundary routing, transactional transit, and inter-system asset transfers, a transit royalty of up to 0.50% is assessed and transferred entirely to the Regeneration Reserve Fund ($S_{reserve}$).

3.5. System Fiscal Matrix

Transaction Type	Total Fee / Split Rate	Net Project Capital Allocation
Inbound Fiscal Split	2.50%	97.50% (T_net Equity)
P2P Barter Swap	1.50%	N/A (Direct Swap)
Transit Royalty	Up to 0.50%	N/A (Transit Routing)

Section 4. Coupling with TSB Clearing Circuit

4.1. Interface Bridge Framework

In accordance with updated systemic standards, heavy legacy corporate Special Purpose Vehicle (SPV) 51/49 banking structures are fully superseded. Section 4 establishes a concise interface bridge connecting Stage 3 approved initiatives directly to the TSB Clearing circuit.

4.2. Escrow Pool Smart Contracts

Upon completing Stage 3 approval, the practical initiative is automatically transformed into an escrow pool smart contract topology executed natively via TSB Clearing.

4.3. Non-Custodial Operational Guarantees

- Zero Direct Bank Account Management: Neither Agora nor its core protocol directly holds, manages, or controls corporate bank accounts or fiat reserves.
- Elimination of Corporate SPV Entities: Operational legal liabilities are decoupled from central protocol operations by omitting manual SPV corporate holding layers.

- Algorithmic Execution: Capital deposits, milestone release triggers, escrow disbursements, and yield distributions are executed entirely programmatically via TSB Clearing contracts.

Section 5. Algorithmic Technical Supervision Framework

5.1. Cryptographic Auditability via ZK-Oracles

Algorithmic Technical Supervision utilizes ZK-oracles to pull validated real-world performance metrics, supply chain status updates, and physical delivery indicators onto the blockchain. These proofs confirm physical compliance without disclosing confidential business operation data.

5.2. TEE Node Network Supervision

Hardware-enforced Trusted Execution Environments (TEE) act as non-manipulable computational nodes. They process complex initiative telemetry, verify milestone compliance equations, and trigger contract state changes in isolated compute spaces.

5.3. Real-Time Algorithmic Auditing and Enforcement

- Continuous Telemetry Auditing: Execution metrics are constantly compared against the initial operational baselines established during Stage 1 and validated in Stage 2.
- Dynamic Escrow Controls: Should an initiative deviate from verified operational metrics, the smart contract automatically enforces built-in governance rules, pausing capital disbursements or adjusting escrow conditions until compliance is re-established.
